(54) Title: APPARATUS AND METHOD OF FABRICATING A COMPENSATING ELEMENT FOR WAVEFRONT CORRECTION USING SPATIALLY LOCALIZED CURING OF RESIN MIXTURES

(57) Abstract: An optical wavefront correction plate incorporates a unique, three-dimensional spatial retardation distribution utilizing the index of refraction change of resin mixture in its cured state. The optical wave plate comprises a pair of transparent plates, containing a layer of a monomers and polymerization initiators, such as resin mixture. This resin mixture exhibits a variable index of refraction as a function of the extent of its curing. Curing of the resin mixture may be made by exposure to light, such as ultraviolet light, and may be varied across and through the surface of the resin mixture to create a particular and unique three-dimensional wavefront retardation profile. The optical wave plate provides improved performance in large area mirrors, lenses, telescopes, microscopes, and ophthalmic diagnostic systems.

**APPARATUS AND METHOD OF FABRICATING A
COMPENSATING ELEMENT FOR WAVEFRONT CORRECTION
USING SPATIALLY LOCALIZED CURING OF RESIN MIXTURES**

Background of the Invention

Field of the Invention

[0001] The present invention relates generally to producing optical elements for use in optical systems.

Description of the Related Art

[0002] In many optical systems it is common to assume that the light passing through the system is limited to paraxial rays, specifically, rays that are near the optical axis and that are sustained within small angles. With this assumption, corrective optics having only spherical surfaces can correct aberrations that are present in images generated by the optical systems. While aspheric optics can be produced, to do so is costly and time consuming.

[0003] An example of the above problem is the human eye. It is conventionally assumed that ocular imperfections are limited to lower order imperfections, including the imperfections commonly called "astigmatism" and "defocus", that can be corrected by lenses having spherical surfaces. However, in reality optical systems including the human eye rarely are limited to what is conventionally assumed for purposes of providing corrective optics that have only spherical surfaces. In the case of the human eye, for instance, higher order imperfections can exist, including but not limited to those imperfections known as "coma" and "trefoil". These imperfections unfortunately cannot be corrected by conventional glasses or contact lenses, leaving patients with less than optimum vision even after the best available corrective lenses have been prescribed.

[0004] Moreover, as recognized by the present invention, it is often difficult to simultaneously minimize all aberrations. Indeed, corrections to an optical system to minimize one type of aberration may result in the increase in one of the other aberrations. As but one example, decreasing coma can result in increasing spherical aberrations.

[0005] Furthermore, it is often necessary to correct aberrations in an optical system that are introduced during manufacturing. This process can be iterative and time consuming, requiring, as it does, assembly, alignment, and performance evaluation to identify aberrations, followed by disassembly, polishing or grinding to correct the aberrations, and then reassembling and retest. Several iterations might be needed before a suitable system is developed.

[0006] Having recognized the above-noted problems, the invention provides the below-disclosed solutions to one or more of them.

Summary of the Invention

[0007] The present invention is related to optical elements having a variable and predetermined, three-dimensional spatial retardation distribution and related systems and methods for making such optical elements.

[0008] The optical element of one embodiment of the present invention includes a cavity. The cavity can be formed by a pair of transparent windows, or plates with a retaining ring, or spacer between the plates. The cavity is filled with one or more monomers, or pre-polymers, monomer mixtures and polymerization initiators (referred to generally herein as a resin mixture). This resin mixture exhibits an index of refraction change as it polymerizes, and the change is controlled by the extent of its polymerization, or curing. The curing of the resin mixture may be initiated by exposure to light, such as ultraviolet light. The exposure to light may be controlled spatially across and through the resin mixture to create a predetermined three-dimensional wavefront retardation profile. One application of such a wavefront retardation plate is to cancel the aberrations in an optical system, such that when an ideal plane wave passes through the wavefront retardation plate, a predetermined change of the wavefront profile can be affected by the wave plate, and when the wavefront subsequently passes through the optical system, aberrations introduced by the system (except for the intended focusing of the system) are cancelled. Alternatively, if the goal of the optical system is to establish a cylindrical lens, all aberration terms are cancelled, except for the desired astigmatism terms. Embodiments of the present invention have the ability to produce any retardation, including any one or any combination of the aberrations as describable by the Zernike polynomials.

[0009] The present invention is also applicable to the manufacturing of all conventional and specialized optical elements, including aspheric and other refractive surfaces, refractive elements (e.g., lenses), reflective elements (e.g., mirrors and beam splitters), and/or diffractive elements such as gratings, and Fresnel optics.

Detailed Description

[0027] Referring initially to Figure 1, a correcting element of the present invention is shown, generally designated 10. As shown, the correcting element 10 includes a first rigid or flexible transparent plate 12, a second rigid or flexible transparent plate 14, and a layer of resin mixture 16 sandwiched therebetween. If desired, a barrier 18 can be used to contain the resin mixture 16 between the plates 12, 14 prior to, and following, the below-described curing of the resin mixture.

[0028] The term "resin mixture," as used herein, is intended to include light-curable resins comprised of one or more monomers, pre-polymers, polymers and polymerization initiators. The refractive index of the resin changes as the resin is cured, and it can be made to vary between locations within the resin layer depending on the spatial extent of curing of the resin mixture, as more fully disclosed below. The extent of curing is determined by the percentage of cross-linking between the monomers within the resin mixture. One non-limiting example of suitable resins is VLE-4101 UV-Visible Light CureEpoxy, available from Star Technology, Inc., or Optical Adhesive #63, U.V. Curing, available from Norland Products, Inc. Typically, these resins are curable by exposure to UV or visible light radiation in the range of 300 to 550 nanometers (300-550

nm). Generally, any type of material that exhibits an index of refraction change upon curing may be used and the corresponding curing light source may have appropriate curing wavelengths, e.g., wavelengths that are within the range of 250 nm to 3000nm. Alternatively, the resin mixture can be cured by other radiation such as microwave or electron beam.

[0029] It is to be appreciated, however, that many suitable resins exist which exhibit a similar change in its index of refraction upon exposure to light. Other monomers that polymerize into long-chain molecules using photo-initiators may be used. For example, a suitable monomer may be chosen from the family of epoxides, urethanes, thiol-enes, acrylates, cellulose esters, or mercapto-esters, and a broad class of epoxies. Also, for example, a suitable photo-initiator may be chosen from alpha cleavage photoinitiators such as the benzoin ethers, benzil ketals, acetophenones, or phosphine oxides, or hydrogen abstraction photoinitiators such as the benzophenones, thioxanthenes, camphorquinones, or bisimidazole, or cationic photoinitiators such as the aryl diazonium salts, arylsulfonium and aryliodonium salts, or ferrocenium salts. Alternatively, other photoinitiators such as the phenylphosphonium benzophenone salts, aryl tert-butyl peresters, titanocene, or NMM may be used.

[0030] As shown in Figure 1, the second transparent plate 14 includes an outwardly-facing curved surface 20 which may exhibit a pre-existing refractive power. Alternatively, transparent plate 14 may be planar, as represented by the dashed line 22.

[0031] It is to be understood that the resin mixture 16 may be formed with a predetermined thickness "t" such that a predetermined volume is established between the plates 12, 14, and barrier 18. As understood herein, the thickness and/or volume of resin mixture 16 can be established as appropriate to provide a correcting element having any desirable spatial retardation distribution utilizing the index of refraction change of resin mixture in its cured state.

[0032] Referring now to Figure 2, a system generally designated as 24, is shown for curing the resin mixture 16 of the correcting element 10. As shown, the system 24 includes an X-Y-Z scanning unit 26 having an X-direction rail 28 and an Y-direction rail 30. Also, the system 24 includes a Z-direction rail 32 extending from the X- or Y-direction rails. Moreover, a light source 34 having a beam shaping unit 36 is attached to and is movable on the Z-direction rail 32. The beam shaping unit 36 may include spatial filtering and beam collimation components to produce a higher quality beam.

[0033] Figure 2 shows that the light source 34, in combination with the beam shaping unit 36, create a light beam 38 which, in a preferred embodiment, is substantially collimated. It should be appreciated, however, that a non-collimated beam may also be used if desired. In one exemplary, non-limiting embodiment, the light beam 38 passes through a focusing lens 40 to form a converging, or focusing, light beam 42 that is directed toward the correcting element 10, where the light beam 42 passes through the first transparent plate 12 to focus at 44 within the resin mixture

layer 16, as shown and described further below in reference to Figure 7. The focusing lens can be, e.g., a microscope objective piece with a large numerical aperture.

[0034] In any case, in accordance with present principles, the light source 34 irradiates the monomer (e.g., resin mixture 16), which activates the photo-initiator and begins the curing process within the resin mixture 16. The curing process results in a corresponding change of the index of refraction within the resin. Terminating the exposure to the light ceases the curing of the resin mixture, thereby ceasing the change of the index of refraction exhibited by the resin mixture. In this manner, the correcting element 10 is established by exposing predetermined portions of the resin mixture 16 to light.

[0035] As envisioned by the present invention, the activation and power level of the light source 34 and its position along the X-Y-Z axes may be controlled by a controller 46, which is electrically connected to the light source 34 and to shuttling components on the rails 28, and/or 30, and/or 32. The controller 46 can receive instructions regarding the desired index of refraction profile to be implemented from a computer 48 with associated monitor 50. More particularly, by moving the light source 34 along the rails 28, 30, 32 in the directions respectively indicated by arrows 52, 54, 56, and by establishing the power of the light source 34, curing volumes of differing sizes or the same sizes may be formed within the resin mixture 16. For instance, by delivering a lower intensity, or lower power level, from the light source 34, a spatially localized curing that is only immediately adjacent to the focal point 44 can be established, to create a relatively small curing volume. On the other hand, by delivering a higher intensity, or higher power level, from the light source 34, a spatially localized curing may include regions of resin mixture surrounding the focal point 44, to create a larger curing volume. Regardless, the depth in the resin mixture 16 of the focal point 44 is established by appropriately establishing the distance d between focusing lens 40 and resin mixture layer 16.

[0036] In a preferred embodiment, the power density of the light source 34 is controlled by controlling the current to the light source. Or, the amount of light delivered into the resin mixture 16 can be established using a constant light source 34 power level and variable light attenuator methods, including Pockel cells or other polarization rotation means and a polarized discriminator. It is to be understood that other light intensity control methods can also be used.

[0037] In a particularly preferred embodiment, the scanning unit 26 first forms the curing volumes which are farthest from the light source 34, i.e., which are deepest in the resin mixture 16. For instance, the scanning unit 26 would initially position the focal point of the light beam adjacent the bottom plate 14. The advantage of initially curing the resin mixture furthest from the light source is that the curing status of the entire resin mixture volume in the resin mixture layer 16 can be better controlled thereby. This method of photon energy delivery is particularly advantageous in those cases wherein the cured resin mixture becomes partially or substantially opaque at the curing wavelength post-curing, in which case the regions of the resin mixture 16 that

would be behind the cured portion (i.e., furthest away from the light source 34) would otherwise become inaccessible for curing.

[0038] Figures 3 and 4 show related embodiments of another system, generally designated 60, that can be used to direct curing light onto the correcting element 10. A collimated light beam 62 is directed to a first beam scanner 64, which can be a single galvanometric type scanner for one dimensional scans as shown in Figure 3. The light passes through a focussing lens 68 toward the target correcting element.

[0039] Or, two galvanometric scanners 64, 66 can be used as shown in Figure 4, with their scan axes oriented orthogonal to each other, for generating two dimensional scan patterns in the X-Y plane. The scanners 64, 66 are placed close to each other and are positioned approximately at the pupillary plane of a focusing lens 68 with a focal length f_1 , providing a focused spot in the resin mixture. Alternatively, one scanner is positioned at the focal position of lens 68, at a distance of f_1 from the lens, and a relay lens 70 with focal length f_2 is positioned at a distance of f_1+f_2 from the focussing lens 68. Consequently, the lenses 68, 70 establish a telescopic relay unit, with the second scanner unit 66 being positioned at a distance of f_2 from the relay lens 70. If desired, an imaging lens 72 with focal length f_3 can be positioned at a distance of f_3 from the scanner 66, and the imaging lens 72 focuses the light energy into a spot in the resin mixture volume.

[0040] In addition to the exemplary scanning units described above, it is to be appreciated that any three-dimensional beam scanning device including the use of rotating polygon, or resonance scanning mirrors as beam steering elements can be used to direct and focus the irradiating energy.

[0041] Indeed, another embodiment of a system for delivering curing light to specific locations in an resin mixture volume is shown in Figure 5 and generally designated 74. The system 74 shown in Figure 5 varies the location of the light source, shown at point 76, at the object plane, shown at 78. The system 74 includes, for the purpose of illustration, two lenses 80, 82 with focal lengths f_4 and f_5 , respectively, that are respectively positioned a distance of f_4 from the object plane 78 and f_5 from an resin mixture object plane 84. Also, the lenses 80, 82 are separated from each other by a distance equal to the sum of their focal points (i.e., f_4+f_5). The radiation source indicated at 76 has a corresponding image point 86 at the resin mixture object plane 84. Likewise, for an off-axis light source location, e.g., as indicated at 88 on the object plane 78, there is a corresponding point location 90 on the resin mixture image plane 84. Accordingly, by moving the light source in the image plane 78 and by establishing an appropriate distance between the lenses 80, 82, the resin mixture of the present correcting element can be cured at various depths at various locations as appropriate to establish a wavefront correcting element.

[0042] Still another system, generally designated 100, is shown in Figure 6A. As shown, a single light source 102 is positioned adjacent an optical fiber 104, with the emitting, distal, end 106 of the fiber 104 being movable to various desired locations at the object plane of the resin

mixture to be cured. The positioning of the optical fiber is controllable by mechanical positioning means 107 that can include motorized translation stages that are movable in three dimensional (XYZ) space to focus light at the target plane such that the radiation emitted from the fiber is delivered to a corresponding image location at the image plane. In this way, the photon energy is delivered through the imaging system to any desired location in the resin mixture volume.

[0043] Alternatively, Figure 6B shows a system 108 having a bundle of stationary fibers 110, each carrying light from a respective light source 112. The radiation intensity of each of source 112 is controllable by a computer. The fiber bundle configuration enables simultaneous multiple-point curing in the resin mixture, and therefore improves curing efficiency without compromising spatial resolution of the desired profile of the index of refraction change in the resin mixture. After the curing process is completed for each location of the fiber bundle, the fiber bundle is then moved to a different location by mechanical translation means 113 to create the index of refraction profile in the resin mixture.

[0044] Having set forth various apparatus for selectively irradiating the resin mixture 16 of the correcting element 10 shown in Figure 1, reference is now made to Figures 7, 8, and 9, which show details of the resin mixture curing process. As shown in Figure 7, the converging light beam 42 passes through the transparent plate 12 and converges within the resin mixture 16. Specifically, the light ray edges 42A and 42B of the beam 42 converge at a focal point 114 and define a curing volume 116 (Figure 8) that has a so-called "beam waist" 118. The beam volume 116 represents the region in the resin mixture 16 which will be cured by exposure to the converging light beam 42. More specifically, the relatively tight focal point 114 of light beam 42 causes the spatially localized curing of the resin mixture 16 to form the curing volume 116. As set forth above, the light beam scanning apparatus is operated to move the focal point of the light beam to various points in the resin mixture to establish the desired curing pattern (light retardation) profile. Generally speaking, a beam 42 with a cone angle 119 that is in the range of 0.002 radians to 1.5 radians may be used.

[0045] Figure 9 illustrates this. Because the preferred converging beam 42 in the present embodiment is conical in shape, the top view of each curing volume 116 is circular. Looking at Figure 9 it can be appreciated that a series of light beams 42 may be used to form a continuous curing pattern through the resin mixture layer 16. In the event that a continuous curing pattern between successive curing volumes is desired, the distance 120 between curing volumes should be less than the diameter, i.e., the waist 118, of the curing volume 116, thereby establishing an overlap region 122 between adjacent curing volumes 116.

[0046] The size of the beam overlap region 122 can have a crucial effect on the overall homogeneity of the index of refraction of the cured resin mixture 16. In a preferred embodiment, the size of the beam overlap region 122 can vary between ten to seventy five percent (10%-80%) of the size of the beam waist 118 of the adjacent curing volumes. In a particularly preferred, non-

limiting embodiment, the size of the beam overlap region 122 is between forty to sixty percent (40%-60%) of the size of the beam waist 118.

[0047] In one embodiment in which a tightly focused beam 42 configuration is preferred, the beam waist 118 is in the range of twenty microns (20 μm) or less. However, beam waists between 0.1 microns and two hundred microns may be used. For the more demanding situations where the index profile is microscopic in dimensions, a diffraction limited focusing configuration with microscopic objective can be used. As an example, a light source can be used that produces a 350 nm wavelength light beam in conjunction with a beam focusing lens with a numerical aperture of 0.5. With this combination of structure, the beam waist 118 has a length of about 0.86 microns (0.86 μm) in air, and in an resin mixture with an index of refraction of 1.54, as an example, the beam waist is 1.35 microns, with the depth of focus being 0.87 microns below the surface of the resin mixture.

[0048] It is to be understood that the curing volumes 116 within the resin mixture layer 16 can be sequential and contiguous to each other as shown in Figure 9, or the scan sequence may be randomly accessed, such that the new curing location can be isolated from the previous location, with no overlap of the beam waists.

[0049] In contrast to Figure 9, which shows a schematic plan view of a curing profile, Figure 10 schematically illustrates an elevational view of the resin mixture to show an exemplary depth profile that can be achieved to establish a three-dimensional curing pattern profile. As stated above in reference to Figure 2, the deeper regions of the resin mixture 16 preferably are cured first. This causes the formation of a curing volume 124. The focal point of the light beam is then moved as described above in the X-Y plane, thereby establishing a first cured layer 126 within resin mixture layer 16. Then, the depth of the focal point of the light beam is adjusted and the light beam moved in the X-Y plane to establish additional curing layers 128, 130, 132, 134, 136, 138.

[0050] Following the creation of a three-dimensional curing pattern profile shown in Figure 10, excess, uncured resin mixture 140 may be removed from the correcting element 10 using a suitable solvent. Once removed, the volume previously occupied by the uncured resin mixture 140 may be refilled with an optically stable fluid which exhibits no refractive index change when exposed to radiation. Or, the volume may be refilled with same or similar resin mixture without any photo-initiator. Yet again, the volume can be refilled with resin mixture containing curing inhibitor such as phenol, or hydroquinone derivatives, which would inhibit any curing action even the resin mixture is exposed to radiation. As still another alternative, the volume can be refilled with another type of resin mixture having a desirable curing characteristic and with a predetermined index of refraction such that the final index of refraction profile in the wave plate is reached when all resin mixture in the confined volume is substantially cure, and such that exposure to sun light or other radiation shall not alter its refractive index profile. Still again, an optical coating can be

applied on the plates 102, 104 to protect the resin mixture from exposure to a predetermined range of wavelengths that would otherwise cure the resin mixture.

[0051] By removing the uncured resin mixture and replacing its volume with or without an optically stable material, a stable correcting element 10 can be established that resists changes to its index of refraction under long term exposure to light sources. This is particularly useful in environments where the correcting element 10 would be exposed to sunlight or other light sources which might contain wavelengths which would cause further curing of the previously uncured resin mixture 140.

[0052] Figure 11 shows the overall steps set forth above. Commencing at block 142, the aberrations, i.e., the wavefront, sought to be corrected is determined. To determine the wavefront, laser-based measuring techniques can be used. In one exemplary, non-limiting embodiment, wavefront sensing instruments such those manufactured by Visx, Santa Clara, CA, or Zeiss/Humphrey Instruments, Dublin, CA can be used.

[0053] Referring briefly to Figure 12, a wavefront 144 is shown that for illustration is a divergent wave which may consist of spherical, astigmatism and high order aberrations. At an imaginary cross sectional plane 146, the wavefront has intersections located at points 148, 150, 152, 154. The peak of the wavefront is indicated at 156, which is traveling ahead of the intersections 148, 150, 152, 154. The distance between the peak 156 and the intersections is typically expressed in the units of physical distance in space. The peak 156 has a projected point 158 on the plane 146.

[0054] Accordingly, the logic of Figure 11 moves from block 142 to block 160 to map the wave sought to be compensated to a resin mixture curing plan. The retardation profile can be determined, for example, by a computer which receives the determined wave front. The curing plan is used to create a curing profile that will vary the index of refraction of the resin mixture 16 to match the profile of the wave 144 such that a plane wave exits the correcting device 10. An illustrative curing profile is shown in Figure 13, which has a three dimensional distribution profile 162 that is identical that of the profile of the wave 144 shown in Figure 12.

[0055] Specifically, in one preferred, non-limiting embodiment, Software running on a computer would perform the following determination. Assume that the unit of retardation required for an ideal compensation can be calculated as follows. Further assume that the difference Δn of the index of refraction between cured and uncured resin mixture is known (typically in the range of 0.001 to 0.05). The maximum retardation required is the physical distance "d" between the wave 144 peak 156, and its projection point 158 on the plane 146. The required thickness of the resin mixture 16 consequently is at least $d/\Delta n$. In the curing profile for the resin mixture layer 16, the scale of the magnitude of the retardation is such that the magnitude of thickness of the cured resin mixture or the integrated index difference at a profile peak 162 to its projection 164 on a cross-sectional plane 166 is $d/\Delta n$. The effect of such a profile is that the peak 156 of the wave 144 will experience the most retardation, and the wave at the intersections 148, 150, 152, 154 experience no

retardation at corresponding locations 168, 170, 172, 174 of the index profile which are in the uncured portion of the resin mixture 16. Accordingly, the resin mixture is cured such that its index of refraction establishes a profile that matches the profile of the wave sought to be compensated for.

[0056] Once the desired refraction profile is determined at block 160, the logic of Figure 11 can move to block 176 to cure the resin mixture 16 in accordance with the curing plan. As mentioned above, uncured resin mixture can be removed from the correcting element 10.

[0057] In certain embodiments the resin mixture 16 need not necessarily be completely cured, depending on the curing plan. Partially cured resin mixture contributes less in the index of refraction change than a completely cured resin mixture for the same volume. Furthermore, a mixture of completely and partially cured resin mixture may also serve the purpose of wavefront compensation in one embodiment. It is the integrated retardation index of refraction profile, and not the actual physical shape of the cured resin mixture volume, that provides the necessary compensation and retardation of the wavefront.

[0058] The foregoing systems and methods can be useful in providing a stable optical wave plate which may exhibit any retardation level, with any spatial variation. Embodiments are applicable to correct distortion in a light beam of any desirable cross sectional area, and have the ability to correct not just low numbers of wave distortions in the range of a fraction of a wave to a few waves, but to correct up to hundreds of waves, covering an area ranging from less than a millimeter to several hundred millimeters. Embodiments are a stand-alone wavefront distortion corrector, and can include a refractive power correction.

[0059] Indeed, turning to Figures 14-16, various other configurations of the correcting element can be seen. For example, as shown in Figure 14, a mirror 178 has a surface non-flatness of more than one wavelength at 632 nm, generally considered to be of poor optical quality. To compensate, a transparent element 180, which is not necessarily of high surface quality, is used as a cover, and a layer of resin mixture 182 is filled between the transparent cover 180 and the mirror 178. The wavefront aberration of the combined elements is measured and mapped to a profile of a curing profile as described above to render a combined structure having a high optical quality with minimal aberrations. As an additional improvement, the outer surface of the mirror may be coated for UV blocking for stopping further curing and any change of the wavefront profile. Other methods of maintaining the index of refraction profile described earlier are also applicable.

[0060] Figure 15 shows an embodiment of the correcting element configured as a lens 184. A transparent, non-diffractive cover 186 can cover the lens 184 and can have either a convex or a concave shape that closely matches the surface of the lens 184. Neither the lens nor the cover plate need have a high surface quality tolerance. A layer of resin mixture 188 is disposed between the cover 186 and the lens 184 to compensate for imperfections in the lens 184 in accordance with principles set forth above.

[0061] Additionally, the embodiments of the present invention are particularly useful in the construction of improved ophthalmic lenses which have refractive power established in increments of fractions of a wavelength over the entire lens area, such that the lens produces localized wavefront correction tailored to the aberration of the eye of an individual. Figure 16 shows such a correcting element.

[0062] In a preferred embodiment, the aberrations of an eye are measured as described above. The outcomes of this wavefront measurement can include piston, tip, tilt, defocus (spherical power), astigmatism and its axis, and the higher order aberrations describable in Zernike polynomials. The prism (tip, tilt), spherical, and astigmatism components, which are referred to as refractive powers, can be corrected with currently available ophthalmic lens with the best possible match, typically limited to 1/8 diopter increments. The systems described above are then applied to complete the correction of aberrations including the residual of the sphere and astigmatism and the high order aberrations. In Figure 16, a lens system 190 includes a conventional ophthalmic lens 192, a cover lens 194, and a thin layer of resin mixture 196 disposed therebetween. As an example, the conventional lens 192 can be a lens with negative refractive power, typically for myopia patients, and the outer surface of the lens 192, i.e., the surface that is farthest way from the eye, has less curvature than the inner surface. The cover lens 194 may or may not have any focusing power, and it is preferably thin, to minimize the overall thickness of the combined lens system. It has a surface curvature closely matched with that of the outer surface of the conventional lens 192. The combined structure is then measured in accordance with present principles to determine the overall refractive power and aberration including the cover lens 194 and resin mixture 196. This is mapped to a curing plan for the resin mixture 196 by subtracting from the eye measurement the correction and aberration of the combined lens structure to render a residual aberration profile. Then the resin mixture 196 is cured to create an index of refraction profile according to the residual aberration profile to cancel the residual aberration. The area of the ophthalmic lens 190 can be in the range of 3 mm to 70 mm, and not usually less than the pupil size of the patient. The optical center of the lens 190 is then aligned with the entrance of the pupil location on a spectacle frame, and the lens 190 is then cut to the correct size to fit into the spectacle for the patient.

[0063] Another application of embodiments of the present invention are improving the resolution of viewing instruments such as telescopes, microscopes, ophthalmic diagnostic instruments including confocal scanning ophthalmoscopes, and fundus cameras. In all cases, each viewing instrument includes refractive elements such as lenses, reflective elements such as mirrors and beam splitters, and diffractive elements such as gratings and acousto- and electro-optical crystals. The present invention can eliminate costly manufacturing of such apparatus by using less costly optics and by compensating for the attendant residual aberrations with correcting elements such as are described above.

[0064] The aberrations of the selected optical system are first analyzed and measured and then mapped to a resin mixture curing plan for an appropriately configured correcting element, which cancels the wavefront aberrations of the optical system. The optical system being corrected can, if desired, include the aberrations introduced by a particular user's eye, so that these aberrations are also compensated for. In the case of a telescope, a correcting element of the present invention is positioned next to the objective lens of the telescope, where the image rays are approximately collimated. In the case of microscope, a correcting element is positioned next to the eyepiece.

[0065] In the case of fundus camera, which is compensated for similarly to microscope compensation, aberrations of the patient's eye to be examined may limit the resolution of the camera. If so, a correcting element of the present invention is first constructed to cancel the aberrations of the eye under cycloplegia conditions wherein the accommodative muscles of the eye are paralyzed, and a separate correcting element for the correction of the aberrations of the camera is constructed and is permanently attached to the camera.

[0066] Figure 17 shows how a correcting element can be incorporated into a confocal scanning imaging system 200. A collimated light beam 202 from, e.g., a diode laser or a HeNe laser 204, is directed by a beam splitter 206 to a beam scanner unit 208. The beam splitter 206 can be a 50-50 beam splitter or a polarization beam splitter which has an appropriate coating to maximize the reflectivity for the incident and maximized transmission for the returned beam with the appropriate polarization characteristics. The scanner unit 208 has its scanner mirror 210 positioned at the focal point of a focusing lens 212, which has a focal length of f_{10} . The scattered light at a target point 214 is imaged through the lens 212, reflected by the scan mirror 210, and focused by a second lens 218 onto a pin hole 218. The light intensity is detected by a detector 220, and is recorded at each target position and processed for the reconstruction of a profile of the target. For two dimensional scanning, two additional relay lenses and a second scanner are inserted between the first scanner 208 and the focusing lens 212.

[0067] To attain improved performance of the system 200, a correcting element 222 in accordance with the foregoing teachings is positioned in the light path to correct the wavefront aberrations introduced by one or more of the above-mentioned components. Likewise, a correcting element can be positioned in the light path if desired.

[0068] Now referring to Figure 18, another application of an embodiment of the present invention is to provide customized progressive addition lenses (PAL) for presbyopic patients. Current progressive addition lenses have a fixed distance between the optical center for the distant vision and that of the near vision. Typically, the patient is fitted for the distant vision for a specific glasses frame of patient's choice. The patient must adapt to a specific viewing angle, by tilting of the head in order to find the best viewing angle for the near vision. This makes the

experience of wearing the progressive addition lens unpleasant for a period of weeks or up to several months before the patient becomes accustomed to the lens.

[0069] With the above considerations in mind, a video image capture setup as shown in Figure 18 can be used to capture the point of intercept of the patient's visual axis with a lens 922 in a trial frame 924 or in a frame selected by the patient. A video camera 910 is positioned at about 90 degrees from the line of sight 920 towards a standard test eye chart 930, and a beam splitter 940 is positioned in the line of sight and is oriented at about 45 degrees to direct an image en face to the patient's eye and the spectacle frame to the camera 910. The camera and the beam splitter can be positioned at any convenient location between the patient and the test eye chart. When the patient is examined in dim light conditions, additional near-infrared illumination at wavelengths longer than 700 nm may be applied to illuminate the eye for ensuring an adequate signal to the camera. The beam splitter may be coated for high transmission for the visible spectrum and for high reflectivity at the near infrared wavelength at 45 degrees. Depending on the location of choice of the camera, a zoom lens may be part of the focusing elements of the camera to bring in the image of the eye and the eyeglasses frame to sufficiently fill the image sensor of the camera.

[0070] The camera 910 first captures the location of the center of the pupil relative to the bottom of the eyeglasses frame when the patient is looking at a distant object (eye chart) 930. A second camera 960 positioned and pointed at the side of the patient head (90E en face) captures the tilt angle of the patient's head when the patient is reading a distant chart or object. The patient is instructed to view the distant object in a most comfortable and natural position. At that point, either the patient or the examiner pushes a switch in a trigger control 970 connected to the cameras 910 and 960 to record the relevant positions and angles in video images from the cameras 910 and 960.

[0071] For the near viewing measurements, the patient is then asked to read a book page, which is disposed at his natural reading position. Depending on the patient's need, the patient instead may be asked to view a display on a computer monitor. The camera 910 captures the change in the convergence of the eyeballs when patient is reading at a near distance. The camera 960 now captures the head tilt angle and the distance between the apex of the cornea to the spectacle lens, using a zoom feature of the camera, and the position of the reading material at the near viewing position without camera zooming. To more accurately pinpoint the patient's line of sight at the near viewing, the patient may be instructed to hold a printed page 990 and read a line at the center on the printed page, and the reading material can be sufficiently reduced in size to reduce variability. The tilt angle of the head can be deduced from the landmarks on the patient's head/ear, or two markers 980, 985 can be placed on the patient's head in near vertical alignment with a headband 987 for example.

[0072] Data analysis from the video images identify the tilt angle of the head at both distant viewing and near viewing, and the angle of the line of sight of the near viewing relative to that of distant viewing. The differences of the angles between the lines of sight and the respective

tilt angles of the head correspond to the amount of eye rotation when the patient changes from distant to near viewing. From the apex distance of the spectacle lens, and the angle of the eyeball rotation, the actual distance between the distant optical center and the near optical center on the spectacle lens can be determined. This distance is unique and customized to the patient, since such a separation distance of the optical centers of the near and distant zones on the spectacle lens and their locations are customized for the natural reading and viewing habits of the patient, and the pupillary distances at the distant and near viewing.

[0073] The foregoing teachings are then applied to construct the added power of the progressive addition lens for the near viewing to the ophthalmic lens, using customized locations of the optical center for the distant viewing and the optical center for the near viewing for that patient. The design of the added power for a progressive addition lens is well known in the art. Alternatively lens design services can be obtained through lens providers such as Shamir Optical of Israel. The power profile of the progressive addition lens is then converted into the index of refraction change profile in the resin mixture layer. This eliminates the process which current progressive addition lens manufacturing requires, i.e., the making individual molds for each customized configuration.

[0074] While particular embodiments and examples are shown and described in detail herein it is to be understood they are representative of the subject matter which is broadly contemplated by the present invention, that the scope of the present invention fully encompasses other embodiments which may become obvious to those skilled in the art, and that the scope of the present invention is accordingly to be limited by nothing other than the appended claims

WHAT IS CLAIMED IS:

1. A correcting element, comprising:
at least one first transparent element; and
a layer of resin mixture juxtaposed with the transparent element and formed with a plurality of successive curing volumes, wherein the successive curing volumes establish a three-dimensional spatial distribution of an index of refraction profile within the resin mixture.
2. The correcting element of Claim 1, further comprising a second transparent element, wherein the first transparent element and the second transparent element hold the layer of resin mixture therebetween.
3. The correcting element of Claim 2, further comprising at least one barrier disposed between the first transparent element and the second transparent element to define a volume of resin mixture.
4. A method for manufacturing a correcting element having a first transparent element, a second transparent element, and a layer of curable, refractive index changing resin mixture sandwiched therebetween, comprising:
determining a three-dimensional spatial distribution of an index of refraction profile;
focussing a light beam on a first location within the resin mixture to establish a first curing volume within the resin mixture; and
refocussing the light beam to one or more subsequent positions within the resin mixture to establish additional curing volumes, wherein the first curing volume and the subsequent curing volumes collectively establish the predetermined three-dimensional spatial distribution of an index of refraction profile.
5. The method of Claim 4, wherein the first curing volume and the subsequent curing volumes establish one or more layers within the layer of resin mixture.
6. The method of Claim 4, further comprising:
determining aberrations in a wavefront; and
determining the three dimensional spatial distribution of an index of refraction profile to compensate for at least some of those aberrations.
7. The method of Claim 4, wherein forming the first curing volume and the subsequent curing volumes further comprises exposing the resin mixture to a light beam having a wavelength suitable for curing the resin mixture.
8. The method of Claim 4, further comprising stabilizing the curing of resin mixture after the profile has been established, the act including removing uncured resin mixture to establish at least one cavity and undertaking at least one of:

- (1) refilling the cavity with an optically stable fluid which exhibits no refractive index change when exposed to radiation;
- (2) refilling the cavity with the same or similar resin mixture without any photo-initiator;
- (3) refilling the cavity with resin mixture containing curing inhibitor, which would inhibit any curing action even the resin mixture is exposed to radiation;
- (4) refilling the cavity with another type of resin mixture having a desirable curing characteristic and with a predetermined index of refraction such that the final index of refraction profile in the wave plate is reached when all resin mixture in the cavity is substantially cured;
- (5) adhering cured resin mixture to the one of the transparent elements; and
- (6) applying highly absorptive or highly reflective coatings on the surface of the first and second transparent elements to protect the resin mixture from exposure to at least some light.

9. An apparatus for manufacturing a correcting element having at least one transparent element and an adjacent resin mixture layer wherein the resin mixture is curable upon exposure to radiation having a wavelength to render cured resin mixture, and the cured resin mixture creates a predetermined three-dimensional spatial distribution of an index of refraction profile, the apparatus comprising:

- at least one scanning unit;
- at least one light source coupled to the scanning unit and emitting a light beam containing the wavelength, the light beam converging to a focal point;
- a means for controlling the scanning unit to position the focal point within the resin mixture layer; and
- a means for controlling the scanning unit to move the focal point through the resin mixture layer to cure the resin mixture, the cured resin mixture establishing the predetermined three-dimensional spatial distribution of an index of refraction profile.

10. The apparatus of Claim 9, wherein at least one of the scanning units is attached to a distal end of the light source.

11. The apparatus of Claim 9, wherein at least one of the scanning unit is attached to the correcting element.

12. An apparatus for manufacturing a correcting element having at least one transparent element and an resin mixture layer wherein the resin mixture is curable upon exposure to radiation having a wavelength to establish a predetermined three-dimensional spatial distribution of index of refraction profile, the apparatus comprising:

- at least one optical fiber coupled to a radiation source, providing a suitable light source for curing the resin mixture;

at least one optical relay imaging a target plane at an emitting end of the fiber to an image plane at the resin mixture layer; and

at least one X-Y-Z translation mechanism attached to the fiber and positioning the fiber at the target plane such that the radiation emitted from the fiber is delivered by the optical relay to a corresponding image location at the image plane.

13. An apparatus for manufacturing a correcting element having at least one transparent element and an adjacent resin mixture layer wherein the resin mixture is curable upon exposure to radiation having a wavelength, and the cured resin mixture creates a predetermined three-dimensional spatial distribution of index of refraction, the apparatus comprising:

an optical fiber bundle;

a plurality of radiation sources, each source being coupled to at least one optical fiber in the bundle;

a plurality of control units controlling the radiation intensity and the duration of the radiation for each source; and

at least one optical relay imaging light from emitting ends of the fiber bundle to a target plane in the resin mixture layer.

14. The apparatus of Claim 13, further comprising a translation mechanism attached to the fiber bundle providing translational positioning of the fiber bundle in at least one dimension in space.

15. A method for improving the performance of an optical instrument, comprising:

determining optical aberrations of the optical instrument;

determining a three dimensional spatial distribution of an index of refraction profile that compensates for the aberrations;

providing at least one correcting element having a layer of curable, refractive index changing material, the providing act including:

(a) directing a focusing light beam to a first position within the layer of material to form a curing volume within the material; and

(b) moving the focusing light beam to one or more subsequent positions within the layer of material to form one or more subsequent curing volumes, wherein the curing volume and the subsequent curing volumes collectively form the predetermined three-dimensional spatial distribution of an index of refraction; and

inserting the wave plate in a predetermined location of the instrument.

16. The method of Claim 15, wherein the instrument is chosen from the group including telescopes, microscopes, confocal scanning microscopes, fundus cameras.

17. A method of improving the performance of an optical element, comprising:
making a correcting element having a first transparent element, and a layer of curable, refractive index changing polymer sandwiched between the first transparent element and a first surface of the optical element, the making act comprising:
- (a) determining optical aberrations of the optical element, the polymer layer, and the first transparent element;
 - (b) determining a three dimensional spatial distribution of an index of refraction profile to compensate for the aberrations;
 - (c) positioning a focusing light beam to a first position within the layer of polymer to form a curing volume within the polymer; and
 - (d) moving the focusing light beam to one or more subsequent positions within the layer of polymer to form one or more subsequent curing volumes wherein the curing volume and the subsequent curing volumes collectively form the predetermined three dimensional spatial distribution of an index of refraction.
18. The method of Claim 17, wherein the optical element is selected from the group including mirrors and lenses.
19. A method of manufacturing a customized ophthalmic lens for a patient, comprising:
- determining aberrations of the eye of a patient;
 - determining a location of a center of an entrance pupil of the eye relative to a spectacle frame;
 - manufacturing a correcting element comprising a first transparent element, and a layer of curable, refractive index changing resin mixture, the manufacturing act including:
 - (a) determining a three dimensional spatial distribution of an index of refraction profile compensating for the aberrations;
 - (b) positioning a focusing light beam to a first position within the layer of polymer to form a curing volume within the resin mixture;
 - (c) moving the focusing light beam to one or more subsequent positions within the layer of polymer to form one or more subsequent curing volumes wherein the curing volume and the subsequent curing volumes collectively form the predetermined three dimensional spatial distribution of an index of refraction profile.
20. The method of Claim 19, comprising aligning an optical center of the correcting element with the center of the entrance pupil in the spectacle frame.
21. The method of Claim 19, comprising cutting the correcting element and fitting the correcting element into the spectacle frame.

22. The method of Claim 19, wherein the aberrations comprise refractive powers and higher order aberrations, the refractive powers comprising spherical power, cylindrical power and its orientation axis.

23. The method of Claim 22, wherein the corrective element comprising a second transparent element, sandwiching the index changing resin mixture between the first transparent element and the second transparent element.

24. The method of Claim 23, wherein at least one of the first and the second transparent element has a refractive power including a spherical and cylindrical power that closely matches corresponding components in the aberrations.

25. The method of Claim 24, wherein determining the three dimensional spatial distribution of an index of refraction profile comprises:

- determining a compensating wavefront of the patient's eye;

- determining a compensating wavefront of the corrective element;

- subtracting the compensation wavefront of the corrective element from the compensating wavefront of the patient's eye to render a residual compensating wavefront representing residual refractive power and high order aberrations of the eye.

26. The method of Claim 24, wherein the area on the ophthalmic lens correcting for the residual aberrations has a diameter in the range of 3 mm-70 mm.

27. A method of manufacturing progressive ophthalmic lenses customized to a patient's eye comprising:

- imaging en face for measuring the patient's pupils, his spectacle, and pupillary distance of the patient when the patient is presented with targets at distant and at near viewing locations;

- imaging 90 degrees en face for measuring tilt angles of the patient's head, a distance between a corneal apex to an ophthalmic lens, and a location of targets when the patient is presented with targets at distant and near viewing locations;

- calculating locations of optical centers on the ophthalmic lens for the patient's distant and near vision; and

- designing a progressive addition lens using the locations of the optical centers of the distant and near vision of the patient.

28. The method of Claim 27, further comprising:

- determining a spatial distribution of an index of refraction profile from a progressive addition lens design;

- positioning a focusing light beam to a first position within the layer of resin mixture to form a curing volume within the resin mixture; and

- moving the focusing light beam to one or more subsequent positions within the layer of resin mixture to form one or more subsequent curing volumes wherein the curing

volume and the subsequent curing volumes collectively form the three-dimensional spatial distribution of an index of refraction.

29. The method of Claim 27, wherein the targets at patient's near viewing positions comprise a display on a computer monitor or printed material at hand-held distance.

30. A method for compensating for aberrations in a wavefront, comprising:
measuring the aberrations in the wavefront;
converting the aberrations to a compensating index of refraction profile;
curing a substance to alter its index of refraction such that the index of refraction establishes a profile that matches the profile of the wavefront sought to be compensated for.

31. An apparatus for curing at least one monomer in a resin mixture at a plurality of cure locations to thereby establish an index of refraction profile in the resin mixture, comprising:

at least one light source useful for curing the monomer;

means for passing light from the light source to at least one of the plurality of cure locations in the resin mixture; and

means for moving the light from one cure location to another cure location.

32. The apparatus Claim of 31, wherein the nearest neighbor cure locations have no overlap.

33. The apparatus Claim of 31, wherein the nearest neighbor cure locations overlap not more than 80% of the beam waist of the light.

34. The apparatus Claim of 31, wherein the nearest neighbor cure locations overlap between 40 to 60% of the beam waist of the light.
